

Work Behaviour Profile Summary

Scope

- Candidate URL: <https://github.com/MitchellQuinn>
- Repositories reviewed: 5 (workovercv, agent-working-ledger, skilldoctor, claimlint, bounded-monocular-perception)
- Artifacts reviewed: 923
- Analysis model information: Deterministic WorkOverCV rubric analysis; no LLM model used.
- Limitation note: Public GitHub evidence is incomplete; this is not a hiring decision record; private/company work may not be visible.

Executive Work Profile

Across 923 collected artifact(s) from 5 repository record(s), the reviewed work suggests an engineer who tends to make technical work inspectable: project purpose, boundaries, reviewer context, and packaging are repeatedly externalised into durable artifacts. The strongest pattern is systems-oriented work made reviewable through runnable code surfaces, tests, metrics, manifests, or evaluation records, project structure that supports later modification, and experiment, model, notebook, or failure-analysis traces. Confidence is strongest for documentation and handoff habits, system-boundary habits, implementation habits, and validation habits. Public evidence remains weaker for live collaboration, operational pressure, and private or company work unless those traces are present in the collected corpus. Evidence gaps are explicit: 3 follow-up area(s) bound interpretation rather than serving as adverse conclusions.

Representative evidence paths include `mittchellquinn-workovercv/README.md`, `mittchellquinn-workovercv/docs/adapter_contract.md`, `mittchellquinn-skilldoctor/docs/architecture.md`. Use the evidence gaps below to clarify what the public corpus cannot show.

Top Observed Work Behaviour Signals

Makes technical work inspectable for reviewers

- Evidence: Reviewer-facing documentation explains purpose, usage, boundaries, or operating assumptions. The evidence bundle contains 5 artifacts across 3 repositories, including readme, technical writeup, and architecture document; reviewers can quickly understand purpose, setup, and stated limits.
- Implication: This suggests a working style that values external legibility, explicit context, and reviewer handoff.
- Confidence: high
- Example evidence paths: `mittchellquinn-workovercv/README.md`; `mittchellquinn-workovercv/docs/adapter_contract.md`

Externalises system boundaries and contracts

- Evidence: Architecture, contract, and configuration artifacts expose design intent, workflow boundaries, or runtime interfaces. The evidence bundle contains 5 artifacts across 4 repositories, including architecture document, technical writeup, and configuration file; technical reviewers can probe design tradeoffs and ownership boundaries.
- Implication: This suggests a tendency to make system shape and operating constraints explicit before or during implementation.
- Confidence: high
- Example evidence paths: `mittchellquinn-skilldoctor/docs/architecture.md`; `mittchellquinn-workovercv/docs/adapter_contract.md`

Translates ideas into runnable, inspectable systems

- Evidence: Implementation artifacts expose concrete runtime behavior rather than only project descriptions. The evidence bundle contains 5 artifacts across 3 repositories, including source code, inference script, and training script; technical reviewers can inspect how ideas are translated into runnable code.
- Implication: This suggests a working style oriented toward executable artifacts that reviewers can inspect and run.
- Confidence: high
- Example evidence paths: `mittchellquinn-bounded-monocular-perception/scripts/analyze_brightness_run.py`; `mittchellquinn-skilldoctor/src/skill_doctor/infer_contract.py`

Prefers measured evidence over assertion

- Evidence: Evaluation, model, run, or data manifest artifacts make measurement workflow and benchmark context inspectable. The evidence bundle contains 5 artifacts across 3 repositories, including evaluation script, model card, and run manifest; applied-ML reviewers can ask targeted questions about metric validity and evaluation design.
- Implication: This suggests a tendency to support technical claims with measurement artifacts and reproducibility context.
- Confidence: high
- Example evidence paths: `mittchellquinn-bounded-monocular-perception/03_rb-training-v2.0/src/evaluate.py`; `mittchellquinn-bounded-monocular-perception/06_live-inference_v0.1/models/distance-orientation/260504-1100_ts-2d-cnn__run_0001/model_card.md`

Structures projects for modification and handoff

- Evidence: Configuration, source organization, and supporting documentation expose maintainability-relevant project structure. The evidence bundle contains 5 artifacts across 4 repositories, including configuration file, source code, technical writeup, and architecture document; founders can inspect whether the work is organized for handoff and repeated modification.
- Implication: This suggests attention to project shape, repeatable setup, and future modification.
- Confidence: high

- Example evidence paths: `mittchellquinn-workovercv/pyproject.toml`; `mittchellquinn-bounded-monocular-perception/02_synthetic-data-processing-v4.0/rb_pipeline_v4/config.py`

Packages technical work so other people can understand and interrogate it

- Evidence: Product or reviewer-positioning artifacts show how the work is packaged, explained, or made usable by others. The evidence bundle contains 5 artifacts across 4 repositories, including readme, technical writeup, and configuration file; reviewers can identify whether the work is framed for users, reviewers, or adapter consumers.
- Implication: This suggests attention to audience, usage context, and public inspectability.
- Confidence: high
- Example evidence paths: `mittchellquinn-workovercv/README.md`; `mittchellquinn-workovercv/docs/adapter_contract.md`

Problem-Solving Style

The reviewed work suggests a problem-solving style that turns uncertain technical spaces into bounded, inspectable systems. Ambiguity is narrowed through explicit boundaries, runnable implementations, checks, metrics, or reproducibility records, and experiment or failure-analysis traces. Where exploratory artifacts are present, the work leaves assumptions, failure modes, or measurement context available for review rather than relying on broad unsupported claims. This supports a research-adjacent engineering profile: exploratory, but biased toward traceability and falsifiable evidence. Confidence: medium. Caveats: Static repositories do not show live decision-making, WorkOverCV does not execute notebook artifacts, and public evidence cannot fully show collaboration or operational pressure.

Environment Fit

May fit well: - Applied ML, evaluation-heavy, or measurement-oriented teams. - Research-adjacent engineering or ambiguous technical problem spaces. - Tool-building contexts that value documentation, boundaries, and inspectability.

May require follow-up: - Roles where private/company work, live collaboration, or production operation history is essential should probe beyond public repositories. - Recorded evidence gaps should be handled as interview prompts, not adverse conclusions.

Role-Family Discussion Routes

These are role-family conversation routes, not hiring recommendations. Read them with the shared evidence gaps below, especially where public repositories do not show team review, private/company work, or full ownership context.

Shared uncertainty context: Collaboration Visibility Gap, Private And Company Work Visibility Gap, and Development Cadence Visibility Gap.

Software Engineer

- Why it is worth discussing: Software-engineering fit is worth discussing when runnable code, explicit interfaces, validation checks, and project structure appear together in the public artifacts. Supporting evidence covers runnable implementation artifacts, system-boundary artifacts, tests or validation gates, maintainability-oriented project structure, and reviewer-facing documentation.
- Likely contribution: The person would likely contribute inspectable implementation work with clear setup context, bounded interfaces, and reviewable maintenance paths, subject to the recorded evidence gaps.
- Role-specific probe: Ask for a code walkthrough that covers interfaces, error handling, validation, and maintenance tradeoffs.

AI Engineer

- Why it is worth discussing: AI-engineering fit is worth discussing when runnable implementation appears alongside model, data, evaluation, experiment, or validation artifacts. Supporting evidence covers runnable implementation artifacts, measurement and evaluation records, tests or validation gates, system-boundary artifacts, and experiment or failure-analysis traces.
- Likely contribution: The person would likely build inspectable AI-adjacent systems that connect implementation choices to evaluation evidence, data or model assumptions, and validation boundaries, subject to the recorded evidence gaps.
- Role-specific probe: Ask for a walkthrough of one AI-facing feature or pipeline from input assumptions through implementation, evaluation, and failure limits.

Applied ML Engineer

- Why it is worth discussing: Applied-ML fit is worth discussing when model, data, run, or evaluation artifacts make representation choices and measurement context visible. Supporting evidence covers measurement and evaluation records, experiment or failure-analysis traces, runnable implementation artifacts, and reviewer-facing documentation.
- Likely contribution: The person would likely turn model or data work into reproducible engineering artifacts with measurable claims and reviewer-visible assumptions, subject to the recorded evidence gaps.
- Role-specific probe: Ask how one metric, dataset, or model-card claim was chosen, validated, and revised.

Research Engineer

- Why it is worth discussing: Research-engineering fit is worth discussing when exploratory artifacts preserve assumptions, rejected paths, experiment traces, or bounded technical claims. Supporting evidence covers experiment or failure-analysis traces, measurement and evaluation records, system-boundary artifacts, and reviewer-facing documentation.
- Likely contribution: The person would likely move exploratory technical ideas toward runnable, traceable prototypes without losing evidence boundaries, subject to the recorded evidence gaps.
- Role-specific probe: Ask for an experiment walkthrough that covers the uncertainty, rejected paths, and evidence that changed direction.

AI Evaluation Engineer

- Why it is worth discussing: AI-evaluation fit is worth discussing when claims are paired with metrics, checks, reproducibility context, or explicit evidence limits. Supporting evidence covers measurement and evaluation records, tests or validation gates, reviewer-facing documentation, and experiment or failure-analysis traces.
- Likely contribution: The person would likely make evaluation work auditable by connecting claims to metrics, manifests, checks, and explicit limitations, subject to the recorded evidence gaps.
- Role-specific probe: Ask for a claims-audit walkthrough that traces an evaluation result back to source evidence and limitations.

Developer Tools Engineer

- Why it is worth discussing: Developer-tools fit is worth discussing when workflows are packaged with command surfaces, adapter contracts, setup documentation, or reviewer context. Supporting evidence covers packaging and usage context, reviewer-facing documentation, runnable implementation artifacts, tests or validation gates, and maintainability-oriented project structure.
- Likely contribution: The person would likely package technical workflows so other engineers can install, inspect, run, and extend them with less hidden context, subject to the recorded evidence gaps.
- Role-specific probe: Ask for a tool-user walkthrough that covers setup friction, extension points, and failure modes.

Evidence Gaps to Clarify

Collaboration Visibility Gap

- Why uncertain: The repository corpus is a public evidence sample and does not expose every work context.
- Follow-up question: Ask for an example of reviewed team work, handoff notes, or pull request discussion.

Private And Company Work Visibility Gap

- Why uncertain: The repository corpus is a public evidence sample and does not expose every work context.
- Follow-up question: Ask which private or workplace projects best represent the same working behaviours.

Development Cadence Visibility Gap

- Why uncertain: The repository corpus is a public evidence sample and does not expose every work context.
- Follow-up question: Ask the person to walk through a representative project timeline and explain major iteration points.

Confidence Notes

- Strongest confidence areas: Makes technical work inspectable for reviewers, Externalises system boundaries and contracts, and Translates ideas into runnable, inspectable systems
- Weaker confidence areas: Signals are drawn from 5 repository record(s); cross-repository confidence depends on how many repositories contain matching artifact types.
- Public evidence limitations: GitHub evidence is a sample of public work, not a complete employment history.
- Private/company work limitations: Private and company work may be absent from the corpus and should be treated as unknown.
